MOTIVATION: previous works

- Increasing use of RCM to evaluate the renewable resource (wind, solar), with previous works indicating a key role of aerosols for such applications.

Differences in PV yearly productivity (in %), averaged by country, for the period 2003–2009 between RCM simulations with and without ARI effects.

► Gutiérrez et al. (2018). Impact of aerosols on the spatiotemporal variability of photovoltaic energy production in the Euro-Mediterranean area. *Solar Energy*, 174, 1142-1152.

- Discrepancies between GCM and RCM future projections for the solar resource.

MOTIVATION: ARI vs. ACI and their scarcely studied effect in RCM long-term experiments

Aerosol-cloud interactions (ACI)

Aerosol-radiation interactions (ARI)

Incoming solar radiation

Direct Effect
Scattering/
absorption

Unperturbed cloud

Semi-direct Effect
Cloud burn-off

1st Indirect Effect
Increased CDNC

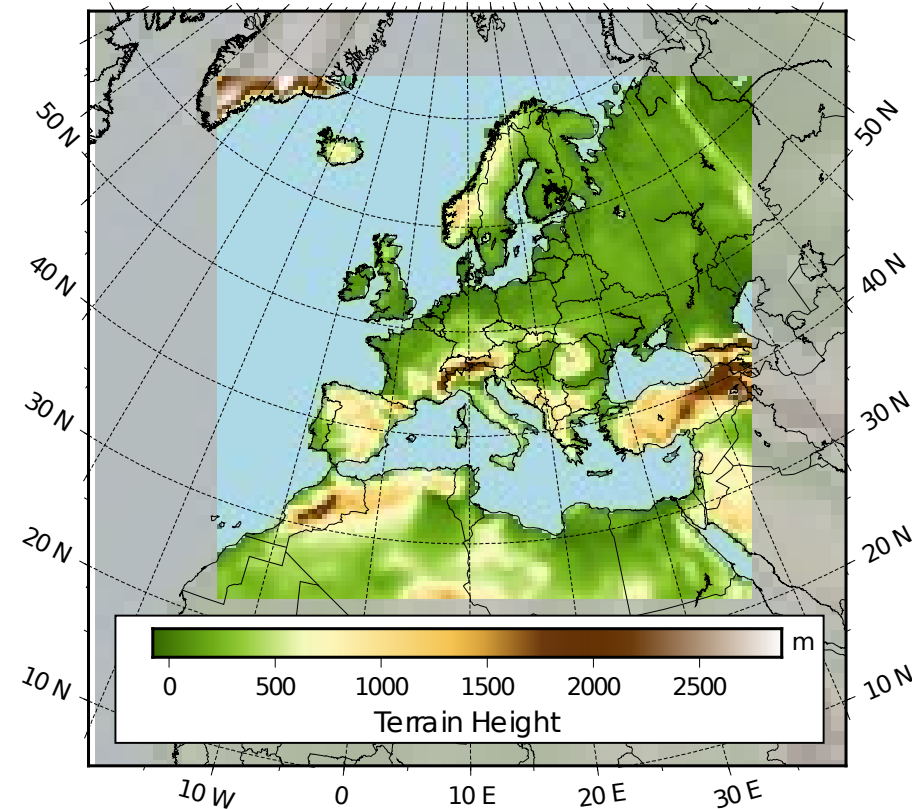

2nd Indirect Effects
Drizzle suppression
Increased cloud height
Increased cloud lifetime

EXPERIMENTS

WRF-Chem was used to downscale **ERA20C** and the CMIP5 **MPI-ESM-LR_r1i1p1** historical and **RCP8.5** runs (performed with the global model ECHAM6) for the periods **1991-2010** and **2031-2050** over an **Euro-Cordex** compliant domain with 0.44° resolution.

Three sets of simulations were performed:

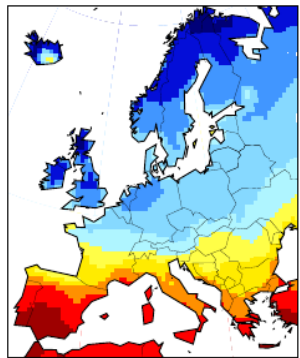

BASE	constant aerosol concentrations without interactions
ARI	variable (online diagnosed) aerosol concentrations, under constant emissions, with aerosol-radiation interactions
ACI	variable (online diagnosed) aerosol concentrations, under constant emissions, with aerosol-cloud interactions

Domain 1 (1.32°) → Saharan dust
Domain 2 (0.44°) → Euro-Cordex

CONCLUSIONS

In present-day simulations, aerosols interactions reduce the amount of solar radiation reaching the surface, both ARI and ACI.

⇒ The reduction is smaller when ACI are included in the RCM execution, because we got less cloud coverage and less AOD as compared to the ARI experiment, so **ACI partly counteracts the ARI effects**.

In terms of future changes, BASE and ARI projections are the most similar between them, with the ARI patterns being the most similar to the patterns retrieved from the driving global simulation. So **ARI certainly reduce the discrepancy between GCM and RCM projections**.

⇒ Again, **the inclusion of ACI counteracts the ARI effects**, not only in the projections for the solar resource, but also for the solar and wind power productivity. As much as that **ARI and ACI projections provide change signals of different sign** in some cases.

Thank you for your attention!
